Understanding the Combined Gas Law

The combined gas law is a fundamental equation in thermodynamics and physical chemistry that describes the behavior of a fixed amount of gas under varying conditions of pressure, volume, and temperature. It combines the three individual gas laws: Boyle's Law (pressure-volume relationship), Charles's Law (volume-temperature relationship), and Gay-Lussac's Law (pressure-temperature relationship). The formula is expressed as:

$$(P_1 \times V_1) / T_1 = (P_2 \times V_2) / T_2$$

where P represents pressure, V represents volume, and T represents temperature in Kelvin. The subscripts 1 and 2 refer to the initial and final states of the gas, respectively. This equation assumes the amount of gas (number of moles) remains constant. Understanding this law is crucial for predicting how gases respond to changes in environmental conditions and for solving related quantitative problems.

Key Variables in the Combined Gas Law

Each variable in the combined gas law plays a specific role:

- **Pressure (P):** The force exerted by gas particles on the walls of the container, typically measured in atmospheres (atm), pascals (Pa), or millimeters of mercury (mmHg).

- **Volume (V):** The space occupied by the gas, usually expressed in liters (L) or milliliters (mL).
- **Temperature (T):** The average kinetic energy of gas particles, measured in Kelvin (K). It is crucial to convert temperatures from Celsius to Kelvin before calculations by adding 273.15.

When to Use the Combined Gas Law

The combined gas law is applicable when the amount of gas is constant but two or more of the pressure, volume, and temperature variables change simultaneously. It is especially useful in scenarios where direct measurement of one state is missing and must be determined based on initial conditions. Typical applications include gas behavior in syringes, balloons, car tires, and weather balloons.

Step-by-Step Approach to Solving Combined Gas Law Problems

Solving combined gas law example problems requires a systematic method to ensure accuracy and clarity. The following steps outline the process:

1. **Identify the Known Variables:** Determine the initial and final pressures (P_1 , P_2), volumes (V_1 , V_2), and temperatures (T_1 , T_2). Ensure temperature values are in Kelvin.
2. **Write the Combined Gas Law Equation:** Use $(P_1 \times V_1) / T_1 = (P_2 \times V_2) / T_2$ as the working formula.
3. **Substitute Known Values:** Plug the known variables into the equation. Leave the unknown variable as a symbol.
4. **Rearrange for the Unknown:** Algebraically solve the equation to isolate the unknown variable.
5. **Calculate the Result:** Perform the arithmetic carefully to obtain the value of the unknown variable.
6. **Check Units and Reasonableness:** Verify that all units are consistent and that the result makes logical sense.

Example of Unit Conversion

Before solving any problem, convert all temperatures to Kelvin by adding 273.15 if given in Celsius. For instance, 25°C becomes 298.15 K. Similarly, ensure pressures and volumes are in consistent units for comparison.

Common Mistakes to Avoid

- Failing to convert temperatures to Kelvin before calculations.
- Mixing pressure units without converting them to the same system.
- Incorrectly rearranging the equation for the unknown variable.
- Neglecting to verify if the amount of gas is constant before applying the combined gas law.

Common Combined Gas Law Example Problems

This section presents several practical combined gas law example problems with detailed solutions to illustrate the application of the formula in different contexts.

Problem 1: Calculating Final Volume

Problem: A gas has an initial volume of 2.0 L at a pressure of 1.0 atm and temperature of 300 K. If the pressure increases to 2.0 atm and the temperature rises to 400 K, what is the final volume of the gas?

Solution:

1. *Identify variables:* $P_1 = 1.0 \text{ atm}$, $V_1 = 2.0 \text{ L}$, $T_1 = 300 \text{ K}$, $P_2 = 2.0 \text{ atm}$, $T_2 = 400 \text{ K}$, $V_2 = ?$
2. *Apply combined gas law:* $(P_1 \times V_1) / T_1 = (P_2 \times V_2) / T_2$
3. *Rearrange for V_2 :* $V_2 = (P_1 \times V_1 \times T_2) / (P_2 \times T_1)$
4. *Substitute values:* $V_2 = (1.0 \text{ atm} \times 2.0 \text{ L} \times 400 \text{ K}) / (2.0 \text{ atm} \times 300 \text{ K}) = (800) / (600) = 1.33 \text{ L}$

The final volume of the gas is 1.33 liters.

Problem 2: Determining Final Pressure

Problem: A 5.0 L gas container at 300 K has a pressure of 1.5 atm. The gas is heated to 450 K, and the volume decreases to 4.0 L. What is the final pressure?

Solution:

1. *Identify variables:* $P_1 = 1.5 \text{ atm}$, $V_1 = 5.0 \text{ L}$, $T_1 = 300 \text{ K}$, $V_2 = 4.0 \text{ L}$, $T_2 = 450 \text{ K}$, $P_2 = ?$
2. *Apply combined gas law:* $(P_1 \times V_1) / T_1 = (P_2 \times V_2) / T_2$
3. *Rearrange for P_2 :* $P_2 = (P_1 \times V_1 \times T_2) / (T_1 \times V_2)$

4. *Substitute values:* $P_2 = (1.5 \text{ atm} \times 5.0 \text{ L} \times 450 \text{ K}) / (300 \text{ K} \times 4.0 \text{ L}) = (3375) / (1200) = 2.81 \text{ atm}$

The final pressure of the gas is 2.81 atmospheres.

Problem 3: Finding Final Temperature

Problem: A balloon initially has a volume of 3.0 L at 1.0 atm and 290 K. It is compressed to 2.0 L, and the pressure increases to 1.5 atm. What is the final temperature of the gas?

Solution:

1. *Identify variables:* $P_1 = 1.0 \text{ atm}$, $V_1 = 3.0 \text{ L}$, $T_1 = 290 \text{ K}$, $P_2 = 1.5 \text{ atm}$, $V_2 = 2.0 \text{ L}$, $T_2 = ?$
2. *Apply combined gas law:* $(P_1 \times V_1) / T_1 = (P_2 \times V_2) / T_2$
3. *Rearrange for T_2 :* $T_2 = (P_2 \times V_2 \times T_1) / (P_1 \times V_1)$
4. *Substitute values:* $T_2 = (1.5 \text{ atm} \times 2.0 \text{ L} \times 290 \text{ K}) / (1.0 \text{ atm} \times 3.0 \text{ L}) = (870) / (3.0) = 290 \text{ K}$

The final temperature remains 290 Kelvin, indicating that despite changes in pressure and volume, the temperature did not change in this scenario.

Tips and Best Practices for Accurate Calculations

Achieving precision and accuracy in combined gas law example problems requires adherence to several best practices and careful attention to detail throughout the problem-solving process.

Maintain Consistent Units

Always convert temperature to Kelvin and ensure pressure and volume units are compatible. Mixing units can lead to incorrect results. For example, do not combine atmospheres with millimeters of mercury without proper conversion.

Double-Check Calculations and Algebraic Manipulation

Carefully rearrange the combined gas law formula to solve for the unknown variable. Errors in algebraic manipulation are common and can compromise the solution. Reviewing each step helps prevent mistakes.

Use Significant Figures Properly

Report answers with the correct number of significant figures based on the precision of the given

data. This practice ensures the scientific integrity of calculations.

Verify Results for Physical Plausibility

Check whether the computed values make sense in the context of the problem. For example, if pressure increases, volume should typically decrease if temperature remains constant, according to Boyle's Law.

- Convert all temperatures to Kelvin before substitution.
- Use consistent units for pressure and volume.
- Rearrange the equation methodically to isolate the unknown.
- Calculate carefully and check for arithmetic errors.
- Interpret results in the context of physical gas behavior.

Frequently Asked Questions

What is the combined gas law formula used in example problems?

The combined gas law formula is $(P_1 \times V_1) / T_1 = (P_2 \times V_2) / T_2$, where P is pressure, V is volume, and T is temperature in Kelvin.

How do you solve a combined gas law problem when given initial and final pressures, volumes, and temperatures?

Use the formula $(P_1 \times V_1) / T_1 = (P_2 \times V_2) / T_2$. Substitute the known values, convert temperatures to Kelvin, and solve for the unknown variable.

Can you provide a simple example problem using the combined gas law?

Sure! If a gas has $P_1 = 2 \text{ atm}$, $V_1 = 3 \text{ L}$, $T_1 = 300 \text{ K}$, and changes to $V_2 = 6 \text{ L}$, $T_2 = 400 \text{ K}$, find P_2 . Using $(2 \times 3)/300 = (P_2 \times 6)/400$, solve for P_2 to get $P_2 = 1 \text{ atm}$.

Why must temperature be in Kelvin when solving combined gas law problems?

Temperature must be in Kelvin because the gas laws are based on absolute temperature, which

starts at absolute zero (0 K). Using Celsius or Fahrenheit would give incorrect results.

How do you handle combined gas law problems when pressure is given in different units?

Convert all pressures to the same unit before using the formula. Common units are atmospheres (atm), pascals (Pa), or mmHg.

What is a real-world example where the combined gas law is applied?

The combined gas law can be used to predict how a balloon's volume changes with altitude as pressure and temperature vary.

How do you check your answer in a combined gas law example problem?

Check that all units are consistent, temperatures are in Kelvin, and that the final value is reasonable given the changes in variables.

Can the combined gas law be used if the amount of gas changes?

No, the combined gas law assumes a constant amount of gas. If the amount changes, use the ideal gas law instead.

How do you approach a combined gas law problem with missing temperature values?

If temperature is missing, you cannot solve the problem directly with the combined gas law. You must be given or calculate the temperature to apply the formula correctly.
